1. Search discovers nodes
Read vector 17; expand list 17;
then read candidate vectors.
2. Layout assigns slots
Example: node 17 → slot 2.
At 512 B: address = base + 1,024.
3. Emit memory requests
One 512-byte vector → 16 reads
of 32 bytes each, plus list reads.
4. Controller services reads
Banks and rows + timing rules
→ completed cycles and row hits.
